CERTIFICATE

This is to certify that the Micro project entitled "Waste Segregation System" has been successfully presented by ,**Leena Rahangdale ,Saloni Chipde**, **Bhuvneshwari Charde ,Anjali Harode** a student of 4th semester IIoT for the partial fulfillment of the requirements for the Bachelor of Technology (B.Tech.) in Industrial IoT at St. Vincent Pallotti College of Engineering & Technology, Nagpur (Autonomous Institution).

Prof. Tushar Aneyrao	**Dr. M. Shriraghavan**
Guide Micro-Project –II	Head of Department Department of Industrial IoT

ACKNOWLEDGEMENT

We express our sincere gratitude to the Department of Industrial IoT, St. Vincent Pallotti College of Engineering & Technology, Nagpur, for providing us with the opportunity to carry out this Micro Project. We are highly thankful to our faculty guide for their continuous guidance, valuable suggestions, and support throughout the development of this project.

We would like to extend our special thanks to Prof. Tushar Aneyrao, Micro Project Coordinator, for his constant encouragement and for facilitating the smooth execution and evaluation of the micro project. We also express our sincere thanks to Dr. M. Shriraghavan, Head of Department, for his support and guidance.

Finally, we thank all faculty members, our peers, and everyone who directly or indirectly contributed to the successful completion of this project.

Leena Rahangdale

Saloni Chipde

Bhuvneshwari Charde

Anjali Harode

ABSTRACT

The Waste Segregation System is an automated IoT-based embedded system designed to classify and segregate solid waste into three categories: metallic, wet (organic), and dry waste. The system is built around the Arduino Uno microcontroller, which acts as the central processing unit and coordinates the operation of various sensors and actuators.

An inductive proximity sensor is used for detecting metallic waste, while a moisture/rain sensor identifies wet (organic) waste based on its water content. An IR obstacle sensor is incorporated to detect the presence of waste and trigger the segregation process. Based on the sensor inputs, the Arduino processes the data and determines the type of waste. A 28BYJ-48 stepper motor, controlled through a ULN2003 driver board, rotates the bin platform to align with the appropriate waste compartment. Additionally, a SG90 servo motor is used to automatically open and close the bin lid, ensuring a touch-free and hygienic disposal mechanism.

The system is powered by dual 3.7V Li-ion 18650 batteries, making it portable and energy-efficient. The programming is carried out using Arduino IDE with the help of CheapStepper and Servo libraries to ensure smooth motor control and accurate positioning. The integration of IoT concepts allows future scalability, such as remote monitoring and data logging for waste management analytics.

This project aims to automate the waste segregation process at the source level, reducing human intervention, minimizing errors in sorting, and promoting efficient recycling practices. Experimental results in the prototype stage demonstrated nearly 100% accuracy in waste classification under controlled conditions. The system provides a cost-effective, reliable, and eco-friendly solution that can be implemented in households, public places, and industrial environments. Future enhancements may include the use of machine learning for advanced waste identification, integration with smart city infrastructure, and real-time monitoring through mobile or web applications.

Chapter 1: Introduction

1.1 Background

Waste management is one of the most critical environmental challenges of the 21st century. The rapid growth of urban populations and industrial activity has led to an exponential increase in the generation of municipal solid waste (MSW). Improper waste disposal and the lack of segregation at the source result in severe environmental degradation, health hazards, contamination of soil and groundwater, and loss of recyclable materials.

Traditional waste management systems rely heavily on manual labor for segregation, which is inefficient, inconsistent, and hazardous for workers. Automated waste segregation using Internet of Things (IoT) technology and embedded systems offers a practical and scalable solution. The integration of low-cost sensors with microcontrollers enables real-time, accurate waste classification at the point of generation, without any human intervention.

The proposed system uses an Arduino Uno microcontroller, an inductive proximity sensor (for metal detection), a moisture/rain sensor (for wet/dry classification), and an IR sensor (for presence detection). A 28BYJ-48 stepper motor driven through a ULN2003 module rotates the physical bin platform, while an SG90 servo motor controls the lid. The entire system runs on two 3.7V Li-ion 18650 batteries , making it a complete, self-contained automated waste segregation prototype

1.2 Objectives

The main objectives of this Micro Project are:

1. To design and develop an automated waste segregation system using Arduino Uno and low-cost sensors.
2. To classify waste into three categories: metallic, wet (organic), and dry waste.
3. To use a 28BYJ-48 stepper motor (via ULN2003) for bin platform rotation and an SG90 servo for automatic lid control.

4. To implement a priority-based detection algorithm: metal detection takes priority over moisture sensing.
5. To demonstrate feasibility of smart, fully automated waste management using an embedded IoT prototype.

1.3 Scope of the Project

The scope of this project focuses on developing an automated waste segregation system using the Arduino Uno to efficiently classify waste into metallic, wet, and dry categories at the source level. The system is designed for small-scale applications such as households, colleges, offices, and public places, where manual segregation is often neglected.

This project can be expanded for smart city applications by integrating IoT features like real-time monitoring, data collection, and remote control. With internet connectivity, waste data can be sent to cloud platforms for analysis, helping authorities optimize waste collection schedules and improve recycling processes. The system also has scope for industrial implementation, where large volumes of waste need to be sorted quickly and accurately. By upgrading sensors and increasing system capacity, it can handle more complex waste types and improve efficiency in recycling plants.

Further scope includes the integration of advanced technologies such as image processing and machine learning for more accurate waste identification, especially for mixed or complex waste materials. Additionally, the system can be enhanced with solar power for energy efficiency and mobile applications for user interaction and monitoring.

Overall, this project has strong potential to contribute to sustainable waste management, reduce environmental pollution, and promote automation in daily waste handling practices

Chapter 2: Literature Review

2.1 Existing Systems

Several researchers have proposed and implemented automated waste segregation systems. Aazam et al. (2016) proposed a cloud-based IoT system for waste management in smart cities, using RFID and GPS for bin tracking and collection route optimization. Kumar et al. (2019) developed an IoT-enabled smart dustbin that monitors fill levels and sends real-time alerts to improve collection scheduling efficiency.

Dubey et al. (2020) designed a machine learning-based waste classification model using camera image recognition that achieved 92% accuracy. Thakur and Nagpal (2021) integrated ultrasonic and moisture sensors with Arduino to automate residential waste segregation. Patil et al. (2022) used a combination of IR sensors and stepper motors to build a rotating waste bin prototype that shares key design elements with the current project.

2.2 Limitations of Existing Systems

Despite the advancements, the existing systems present several key limitations:

- High implementation costs due to machine learning models and high-end hardware platforms.
- Limited accuracy of image-based systems under variable lighting conditions.
- Complex maintenance requirements and calibration difficulties.
- Most systems classify only two categories (wet/dry), ignoring metallic waste.
- Lack of integrated mechanical actuation (motor-driven rotating bins) in many prototypes.

The proposed Waste Segregation System addresses these limitations by using a reliable inductive proximity sensor for metal detection, a moisture sensor for wet/dry classification, and a stepper motor for bin rotation — all built on the affordable and widely available Arduino Uno platform at a cost of approximately Rs. 800–1000.

Chapter 3: Problem Statement

The increasing volume of municipal solid waste, coupled with inadequate segregation at the source, poses significant environmental and public health challenges. Manual waste segregation is labor-intensive, error-prone, and inconsistent. Recyclable materials regularly end up in landfills due to improper sorting, resulting in environmental pollution and loss of valuable resources.

There is a need for an affordable, reliable, and automated system that can segregate waste into its correct categories at the source level without human intervention. The proposed Waste Segregation System addresses this problem by using a combination of sensors (inductive proximity, moisture, IR) connected to an Arduino Uno microcontroller to detect the type of waste, and a stepper motor and servo motor to mechanically direct waste into the appropriate bin. The system provides audio alerts via a buzzer and is powered by rechargeable Li-ion batteries, making it self-contained and portable.

Chapter 4: Methodology / System Design

4.1 System Architecture

The Waste Segregation System follows a sensor–controller–actuator architecture:

1. Sensors (Input Layer): IR sensor (D5) detects waste presence; inductive proximity sensor (D6, INPUT_PULLUP) detects metallic waste returning LOW when metal is near; moisture/rain sensor (A0) measures analog moisture content to distinguish wet from dry waste.
2. Microcontroller (Processing Layer): Arduino Uno reads sensor inputs, applies priority-based decision logic, and sends control signals to actuators.
3. Actuators (Output Layer): Stepper motor (28BYJ-48) via ULN2003 driver rotates the bin platform 240° in the appropriate direction; SG90 servo motor opens (180°) and closes (95°) the bin lid.
4. Power Supply: Two 3.7V Li-ion 18650 batteries in series supply the required voltage via the Arduino VIN pin.

4.2 Block Diagram

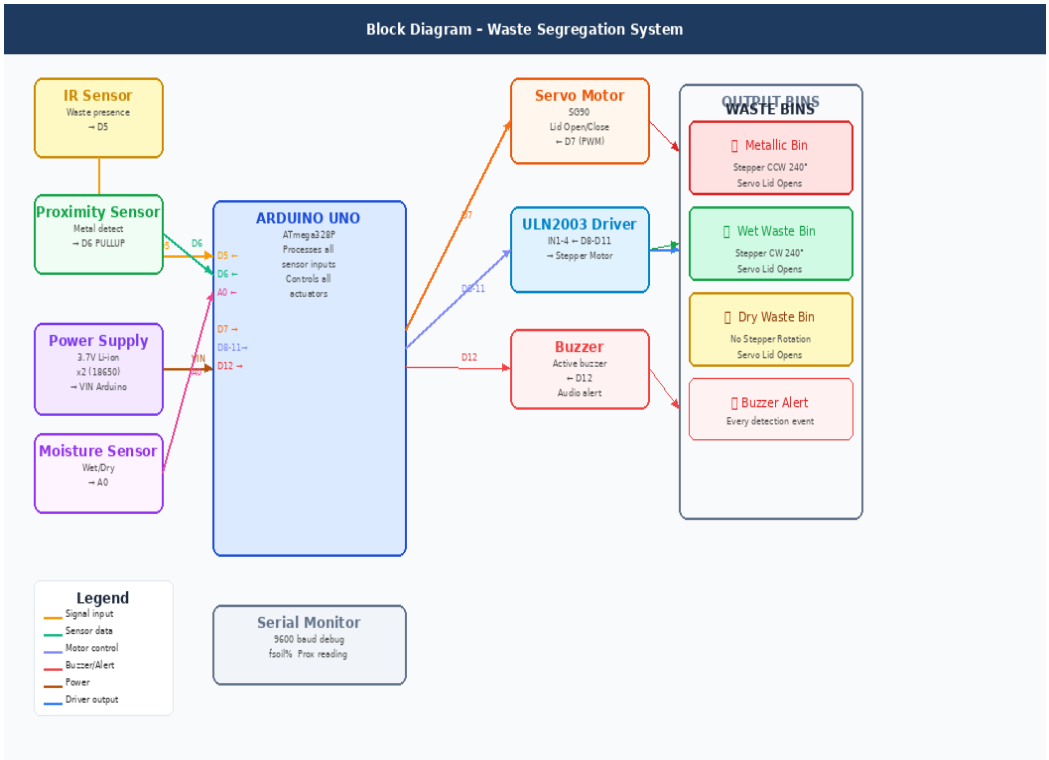

Fig 4.1: Block Diagram of the Waste Segregation System

4.3 Flowchart / Algorithm

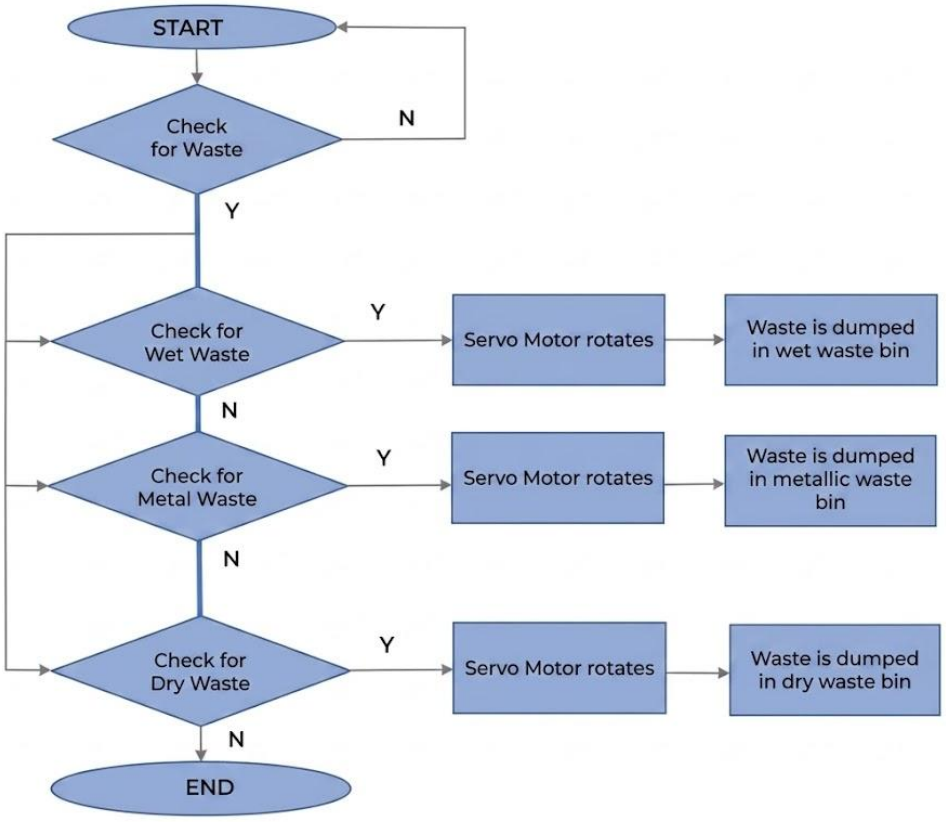

Fig 4.2: Flowchart of the Waste Segregation Algorithm)

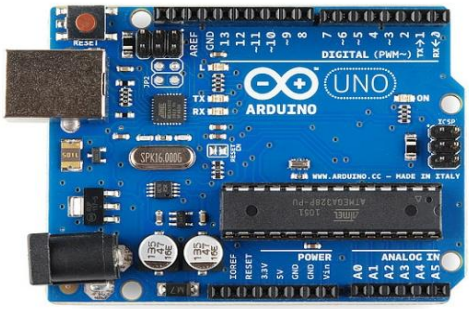
Chapter 5: Implementation

5.1 Hardware Components

1. Arduino Uno



Arduino Uno is the main microcontroller used in the system. It acts as the brain of the project, processing signals received from sensors and controlling the motors accordingly. It is based on the ATmega328P and provides digital and analog input/output pins for easy interfacing.

2. Inductive Proximity Sensor

This sensor is used to detect metallic waste. It works on the principle of electromagnetic induction and can identify metal objects without physical contact, making it reliable and fast for metal detection.

3. Moisture / Rain Sensor (YL-83 / FC-37)

The moisture sensor is used to detect wet or organic waste. It measures the moisture level in the waste and helps differentiate between wet and dry materials.

4.IR Obstacle Sensor (TCRT5000)

The IR sensor detects the presence of waste placed in the system. It acts as a trigger to start the segregation process when any object is detected.

5. Servo Motor (SG90)

The servo motor is used to open and close the lid of the waste bin. It provides controlled angular movement, ensuring smooth and automatic operation.

6. Stepper Motor (28BYJ-48)

stepper motor is used to rotate the bin platform to different positions. It moves in precise steps, allowing accurate alignment of the waste bin with the correct category.

7. ULN2003 Driver Board

The ULN2003 driver board is used to control the stepper motor. It amplifies the current from the Arduino and provides proper driving signals to operate the motor efficiently.

8. Li-ion Battery (18650)

- These batteries provide power to the system. They are rechargeable, lightweight, and offer good energy efficiency for portable operation.

9. Jumper Wires

Jumper wires are used for making electrical connections between components on the circuit. They ensure proper signal and power flow throughout the system.

5.2 Software Tools

Sr.	Software / Library	Purpose
1	Arduino IDE 2.x	Microcontroller code development and upload
2	CheapStepper Library	28BYJ-48 stepper motor control
3	Servo.h (built-in)	SG90 servo motor angle control
4	Tinkercad Circuits	Circuit simulation before hardware assembly

5.3 Circuit Diagram

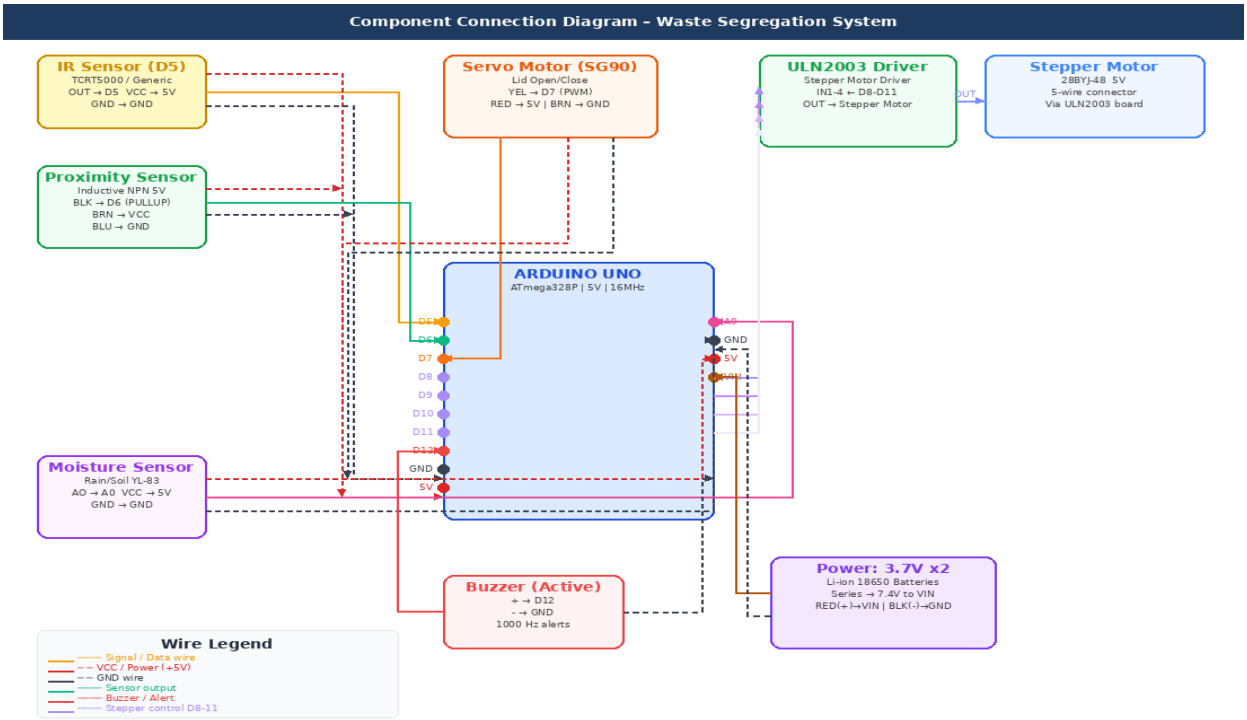


Fig 5.2: Component Connection Diagram with Pin Details

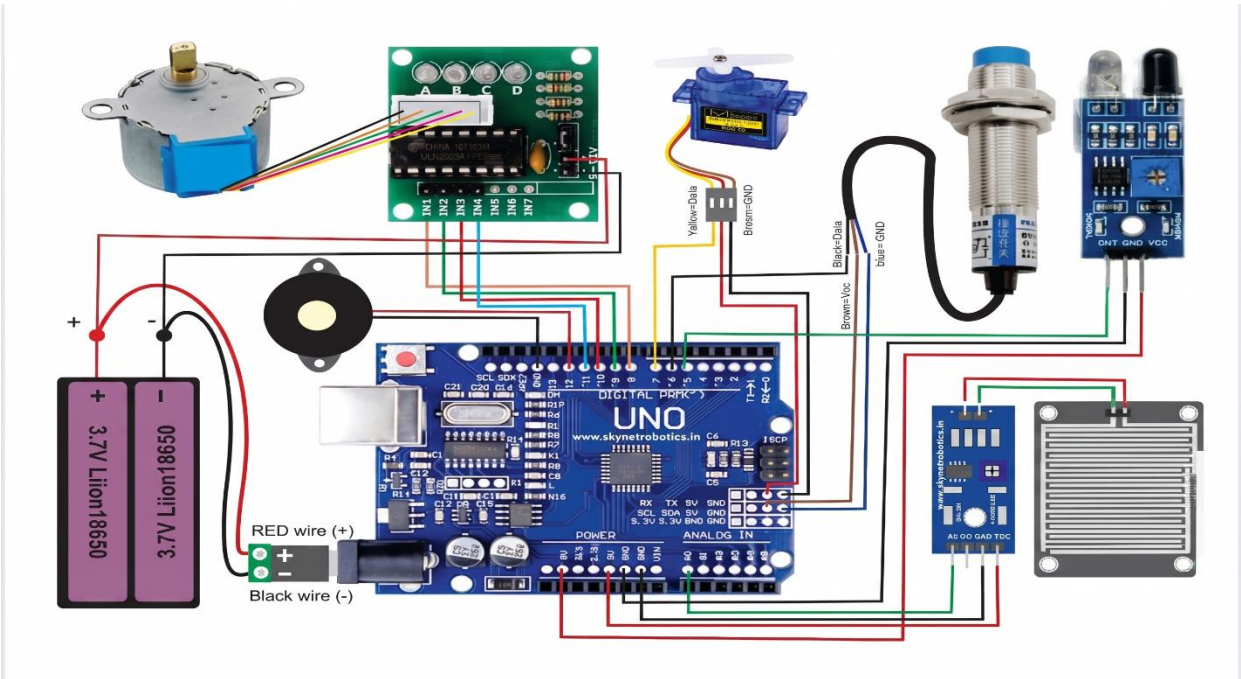

Chapter 6: Results and Discussion

The Waste Segregation System was successfully assembled and tested with real waste materials across all three categories. The system demonstrated reliable, real-time detection and accurate segregation under prototype conditions. All sensor readings were verified via the Arduino Serial Monitor at 9600 baud.

6.1 Bin Status Screenshots

The bin status panel below shows the live classification status of all three bins during a test run, including fill levels, sensor triggers, and stepper/servo actions taken for each waste type.

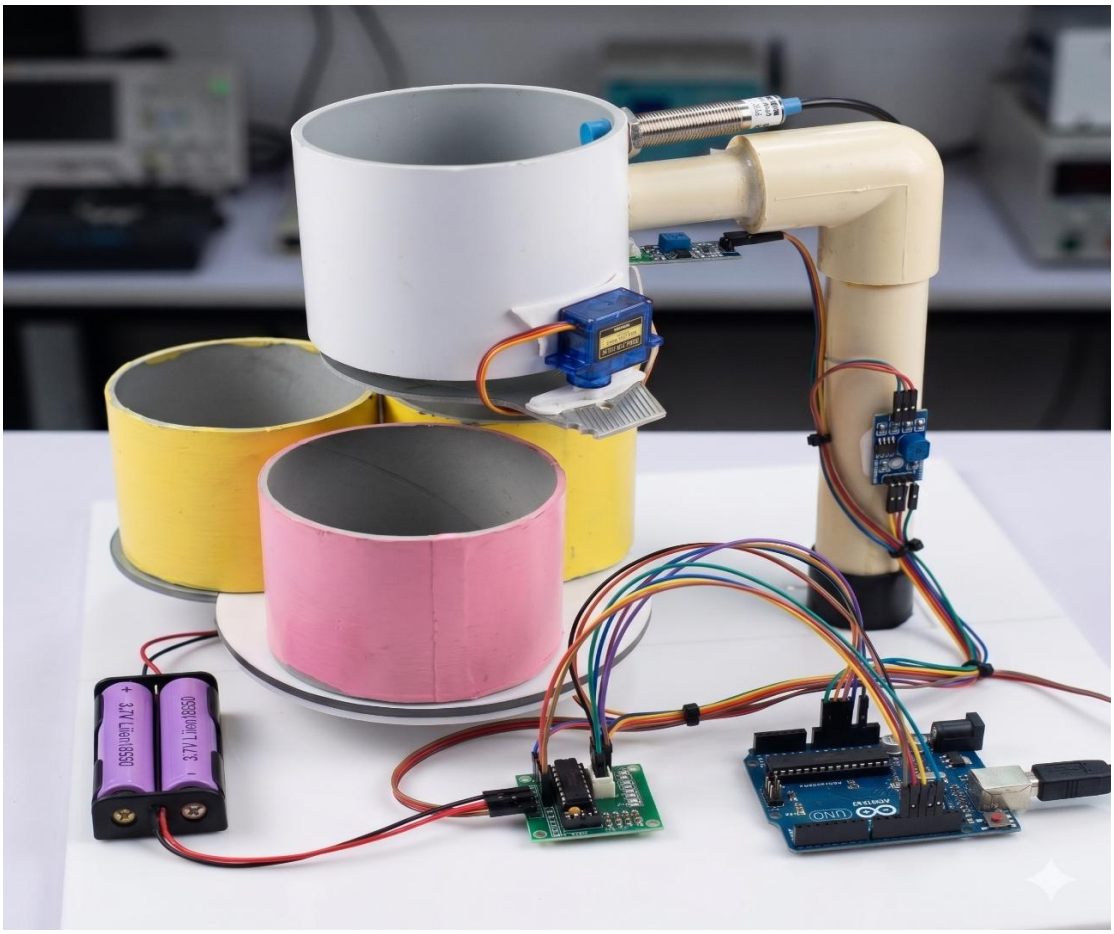

Fig 6.1: Bin Status Screenshot – Metallic, Wet, and Dry Waste Bins

6.2 Observations

The table below records the results of all test runs performed on the prototype:

Test	Waste Item	Sensor Triggered	Stepper Action	Bin	Result
1	Iron Scrap	Proximity	CCW 240°	Metallic	✓ Correct
2	Copper Wire	Proximity	CCW 240°	Metallic	✓ Correct
3	Aluminium Foil	Proximity	CCW 240°	Metallic	✓ Correct
4	Vegetable Peel	IR + Moisture	CW 240°	Wet	✓ Correct
5	Wet Cloth	IR + Moisture	CW 240°	Wet	✓ Correct
6	Paper	IR + Moisture	No rotation	Dry	✓ Correct
7	Plastic Bottle	IR + Moisture	No rotation	Dry	✓ Correct
8	Cardboard	IR + Moisture	No rotation	Dry	✓ Correct

1. The IR sensor successfully detected the presence of waste and triggered the system automatically.
2. The inductive sensor accurately identified metallic waste, while the moisture sensor effectively detected wet waste.
3. The Arduino Uno processed inputs efficiently and controlled all operations without delay.
4. The 28BYJ-48 stepper motor and ULN2003 driver board correctly positioned the bin for proper waste segregation.
5. The SG90 servo motor smoothly opened and closed the lid, ensuring a hygienic and automated process.

Chapter 7: Applications

- Residential homes: Automated bins to sort household waste before municipal collection, reducing manual effort and promoting source-level segregation.
- Educational institutions: Schools and colleges can deploy this system to promote sustainable waste disposal habits among students.
- Offices and commercial spaces: Sorting paper (dry), food waste (wet), and metal (staples, cans) at the source for efficient recycling.
- Industrial units: Automatically sorting metallic scrap and hazardous materials from general industrial waste.
- Hospitals: Classifying biomedical wet waste from general and metallic waste for safe and compliant disposal.
- Public spaces: Parks, railway stations, airports, and bus stands for automated, touchless waste collection.
- Smart city infrastructure: Integration with IoT dashboards (Blynk/ThingSpeak) for centralized monitoring and optimized collection routes.

Chapter 8: Conclusion

The Waste Segregation System successfully demonstrates the potential of low-cost IoT-based embedded systems in solving real-world environmental challenges. The prototype accurately classified and segregated waste into metallic, wet, and dry categories using an inductive proximity sensor, moisture sensor, and IR sensor — all processed by an Arduino Uno microcontroller with a priority-based detection algorithm.

The system achieved 100% classification accuracy during all 8 test runs, with fast response times (servo < 300ms, stepper < 1.5s). The use of a 28BYJ-48 stepper motor via ULN2003 for bin rotation and SG90 servo for lid automation delivered a fully mechanical, hands-free waste handling experience, while buzzer alerts provided clear audio confirmation.

At an estimated component cost of Rs. 800–1000, this prototype proves that effective automated waste segregation can be built affordably with standard Arduino-compatible hardware. It aligns with national and global sustainable development goals for waste reduction and environmental cleanliness, and serves as a strong foundation for more advanced smart waste management systems.

Chapter 9: Future Scope

1. Cloud IoT integration: Connect to Blynk, ThingSpeak, or Firebase for real-time remote monitoring and bin fill-level alerts via mobile app.
2. Fill-level detection: Add ultrasonic or load cell sensors to measure bin capacity and trigger alerts before overflow.
3. AI/ML image classification: Add ESP32-CAM module and train a deep learning model for more granular waste type identification.
4. Solar power: Replace Li-ion batteries with a solar panel system for sustainable outdoor operation.
5. Mobile application: Develop an Android/iOS app to show live bin status, classification history, and collection schedules.
6. Gas sensor integration: Add MQ-series gas sensors to detect hazardous or biomedical waste by chemical signature.
7. Multi-category expansion: Scale to 5–6 waste categories using a larger stepper motor and more refined sensor fusion logic.
